

Coaxial Transmission Lines

Definitions

Mechanical characteristics

Cable weight

Weight per unit (meter or foot) of the complete cable.

Bending properties

A particular advantage of RF cables with corrugated conductors is their flexibility, as expressed in the data for minimum bending radii.

Minimum bending radius, single bending

After the cable has been bent to these minimum values it should not be bent back, as this could result in damage to the cable.

Minimum bending radius, repeated bending

This bending radius allows for several operations and indicates the minimum bending radius during the installation procedure of the cable. It also gives an indication of the minimum reel core radius.

Bending moment

A particular advantage of RF cables with corrugated conductors is their flexibility, as expressed in the bending moment. The cable under test is fixed in a straight support and a perpendicular force is introduced at a certain distance (50 times the cable diameter for LCF, 25 times for SCF and UCF) away from the support. The necessary force to deflect the cable by half this distance multiplied by the distance gives the bending moment.

Flat plate crush strength

Another advantage of the outer conductor corrugation is the fact that it gives the cable a very high crush resistance. If the given values are not exceeded the local impedance change is less than 0.5 Ω . For instance: In order to compress a 90 mm length section of CELLFLEX® LCF158-50 to reduce the local impedance by 0.5 Ω , it is necessary to apply a force of more than 2790 N.

Tensile strength

The tensile strength of RF cables is determined by a typical installation situation when pulling the cable with hoisting grips. In the case of corrugated conductors, tensile strength is naturally less than in the case of smooth conductors. To prevent damage to the cable, when hoisting it into masts or pulling it through ducts, the maximum admissible tensile force stated for the particular cable must not be exceeded. The values are based on a maximum cable elongation by 0.2%. Refer to the installation instructions for further details.

Electrical Properties

Characteristic impedance

The mean value of characteristic impedance is measured at around 200 MHz. The admissible deviation from the nominal value is $\pm 1\%$ to $\pm 4\%$, depending on the cable type.

Relative propagation velocity

This ratio (in percent) is the propagation velocity of the electromagnetic wave inside the cable in relation to propagation velocity in free space. It determines the electrical length of the cable.

Capacitance

The capacitance of RF cables is independent of frequency and is determined by the relative dielectric constant, the effective outer conductor diameter and the effective inner conductor diameter.

Inductance

The inductance of RF cables is slightly frequency-dependent and is determined by the effective outer and inner conductor diameter and the equivalent conducting layer due to the skin effect.

Maximum operating frequency

Up to this frequency, the properties of the cable are within the specifications given unless otherwise stated.

Peak power rating

Peak power rating is the input power for which the peak RF voltage rating is reached, when the cable is operating in its matched condition. Peak power rating is independent of frequency.

RF peak voltage

The RF Peak voltage is limited by the air gap between inner and outer conductor of a coaxial line and the voltage withstand of air. Air is also considered a dielectric for foam cables since there will always be a short section of air line at the interface between foam cable and connector. Depending on the connector used, a smaller connector mating interface can be the limiting factor.

Spark test

Within the production process, the cable jacket is tested by applying a pulsed high voltage to the jacket against the outer conductor. This is to ensure the integrity of the jacket regarding holes, inclusions and thickness.

Coaxial Transmission Lines

DC-resistance inner conductor

This value is the DC-resistance of the inner conductor in ohms per length (ohms/km or ohms/1000ft).

DC-resistance outer conductor

This value is the DC-resistance of the outer conductor in ohms per length (ohms/km or ohms/1000ft).

Storage Temperature

During storage the given temperature range must not be exceeded. Otherwise the cable can be damaged.

Operation Temperature

During operation the given temperature range must not be exceeded. Otherwise the cable can be damaged.

Installation Temperature

During installation the given temperature range must not be exceeded. Otherwise the cable can be damaged.

Foundations

Transmission line parameters

Primary & secondary transmission line parameters

The relation between the primary parameters:

series resistance	R' in Ω/km
inductance	L' in H/km
parallel capacitance	C' in F/km
parallel resistance	G' in S/km

and the secondary parameters:

characteristic impedance	Z_c in Ω
propagation constant	γ
phase constant	β in rad/km
attenuation constant	α in N/km

is given by the following transmission line equations:

$$\gamma = \alpha + j\beta$$

$$\gamma = \sqrt{(R' + j\omega L') \cdot (G' + j\omega C')} \quad (1)$$

$$Z_c = \sqrt{(R' + j\omega L') / (G' + j\omega C')} \quad (2)$$

$$\omega = 2\pi f$$

These equations are valid for the entire frequency range of RF cables up to their cut-off frequency.

At radio frequencies where $R' \ll \omega L'$ and $G' \ll \omega C'$, the transmission line equations take the following form:

$$Z_c = \sqrt{\frac{L'}{C'}} \quad \text{in } \Omega \quad (3)$$

$$\beta = \omega \cdot \sqrt{L' \cdot C'} \quad \text{in rad/km} \quad (4)$$

$$\alpha = (R' / 2) / Z_c + (G' / 2) \cdot Z_c$$

$$= \alpha_R + \alpha_G \quad \text{in nepers/km} \quad (5)$$

$$v_\varphi = 1 / \sqrt{L' \cdot C'} \quad \text{in km/s} \quad (6)$$

α_R - conductor attenuation

α_G - dielectric attenuation

v_φ - propagation velocity

The deviations between equations (3) to (6) as compared to equations (1) and (2) is below 0.1%, as long as

$$D_e \sqrt{f} \geq 140 \quad (7)$$

D_e - electrically equivalent diameter of outer conductor in mm

f - frequency in kHz

Skin effect

At DC, current in a conductor flows with uniform density over the cross section of the conductor. At high frequencies, the current tends to flow only in the conductor surface; the effective conductor cross section decreases and the conductor resistance increases.

At radio frequencies, current flows only in a very thin "skin". Everywhere else the conductors are free from electromagnetic fields. Even very thin walled metal envelopes will, therefore, entirely screen the electromagnetic field within coaxial RF cables at radio frequencies.

Coaxial Transmission Lines

The depth of penetration illustrates the skin effect. It is defined as the thickness of a thin surface layer (assumed to have an even distribution of current flow), having the same resistance as an actual conductor, which is undergoing to the skin effect.

For non-magnetic materials the equivalent conducting layer is

$$\delta = 15,9 / \sqrt{\sigma \cdot f} \quad \text{in mm} \quad (8)$$

σ - conductivity in $\text{m}/\Omega \text{ mm}^2$

f - frequency in kHz

Other than resistance, the skin effect also influences inductance and thereby characteristic impedance and propagation velocity.

Electrical characteristics

Capacitance

The capacitance of RF cables is independent of frequency:

$$C' = \frac{10^{-6} \cdot \epsilon_r}{18 \cdot \ln(D_c / d_c)} \quad \text{in F/km} \quad (9)$$

ϵ_r - relative dielectric constant

D_c - effective outer conductor diameter (capacitive)

d_c - effective inner conductor diameter (capacitive)

Inductance

The inductance of a RF cable is:

$$L' = 2 \cdot 10^{-4} \cdot \ln \frac{D_i + \delta}{d_i - \delta} \quad \text{in H/km} \quad (10)$$

D_i - effective inner conductor diameter (inductive)

d_i - effective inner conductor diameter (inductive)

δ - equivalent conducting layer

At very high frequencies, inductance approaches:

$$L' = 2 \cdot 10^{-4} \cdot \ln(D_i / d_i) \quad \text{in H/km} \quad (11)$$

Characteristic impedance

The characteristic impedance of an RF cable is determined by its inductance and capacity according to equation 3. Because of the influence of the skin effect upon inductance, it also is frequency-dependent.

Characteristic impedance of RF cables is, therefore, understood as the value it approaches for very high frequencies. If we say $D_c \approx D_i = D_e$, $d_c \approx d_i = d_e$

and $\delta \ll d_i$ then

$$Z_c = \frac{60}{\sqrt{\epsilon_r}} \cdot \ln(D_e / d_e) \quad \text{in } \Omega \quad (12)$$

D_e - electrically effective outer conductor diameter

d_e - electrically effective inner conductor diameter

ϵ_r - relative dielectric constant

As frequency falls, the characteristic impedance rises. The relative deviation from the value at very high frequency is approx.

$$\frac{\Delta Z}{Z_c} = \frac{4}{D_e \cdot \sqrt{f}} \quad (13)$$

D_e - electrically effective outer conductor in mm

f - frequency in kHz

Certain electrical properties of an RF cable can be optimized by proper choice of characteristic impedance. For coaxial cables with cylindrical conductors (of the same material) the following optimizations are possible:

	air dielectric cables	solid PE dielectric cables
minimum attenuation	77 ohms	51 ohms
max. operating voltage	60 ohms	40 ohms
max. peak power rating	30 ohms	20 ohms
max. mean power rating	$\approx 50 \text{ ohms}^*$	

*approx. valid for HELIFLEX® transmission lines of larger diameter

Coaxial Transmission Lines

Today, RF coaxial cables are produced mainly with characteristic impedance of 50 ohms and to some extend in 75 ohms.

As the material properties and dimensions of RF cables are not constant along their length, the characteristic impedance will vary with length and deviate from the mean value of characteristic impedance of the particular cable; similarly the mean value will deviate from the nominal value (50 or 75 ohms).

The mean value of characteristic impedance of a cable is defined as follows:

$$Z_m = \frac{I_e}{c_o \cdot C} \quad \text{in ohms} \quad (14)$$

I_e - electrical length in m

c_o - propagation velocity in free space in m/sec

C - capacitance in F

The mean value of characteristic impedance is measured at around 200 MHz. The admissible deviation from the nominal value is $\pm 1\%$ to $\pm 4\%$, depending on the product group.

Uniformity of characteristic impedance

As mentioned, the material properties of RF cables are not uniform along their length and result in small deviations of the characteristic impedance. The impedance step ΔZ at position x of the cable results in reflection factor at the position as follows:

$$r_x = \frac{\Delta Z}{2Z_c} \quad (15)$$

The magnitude and distribution of the various reflections determine their effect upon transmission properties. Two ways are commonly used to judge the effect of impedance variation.

Time domain reflectometry (TDR)

A defined voltage step is fed into the cable and partially reflected at each impedance variation. The display of the reflected energy versus time gives a view upon the local distribution of the inner reflections. The pulse reflection factor at a certain position is the ratio between the voltage of the reflected and the incident pulse. Instead of reflection factor, one can also use the term pulse return loss:

$$A_p = 20 \cdot \log \frac{100}{r_p} \quad \text{in dB} \quad (16)$$

r_p - pulse reflection factor in %

The magnitude and nature of the pulse reflection factor depend very much upon the form of incident pulse.

Return loss/reflection factor (steady state condition)

The reflection factor sums up the effects of all the impedance variations within the cable and its ends, at a certain frequency. It is the ratio between the (vectorial) addition of all reflections and the incident signal, measured at the near end of the cable.

As well as reflection factor, the term return loss is also used.

$$A_z = 20 \cdot \log \frac{100}{r} \quad \text{in dB} \quad (17)$$

r - reflection factor in %

The reflection factor versus frequency may be plotted continuously. The reference impedance of test equipment and the load at cable end are equal to the nominal value of cable impedance.

It is also customary to use the term voltage standing wave ratio (VSWR), based upon the standing wave, which the cable under test would produce in a homogeneous transmission line connected to its near end and having its nominal characteristic impedance.

$$S = \frac{1 + r / 100}{1 - r / 100} \quad (18)$$

$$r = \frac{S - 1}{S + 1} \cdot 100 \quad \text{in \%} \quad (19)$$

S - standing wave ratio

Relative propagation velocity and delay

The relative propagation velocity is defined as follows.

$$v_r = \frac{v_\varphi}{c_o} \cdot 100 = \frac{l}{l_e} \cdot 100 \quad \text{in \%} \quad (20)$$

v_φ - propagation velocity in cable

Coaxial Transmission Lines

C_o - propagation velocity in free space ($300 \cdot 10^3$ km/s)

l - geometrical length in m

l_e - electrical length in m

Delay is defined as follows:

$$t_\varphi = \frac{333,6}{v_r} = \frac{10^8}{v_r \cdot C_o} \quad \text{in ns/m} \quad (21)$$

v_r - relative propagation velocity in %

Due to the skin effect, propagation velocity is frequency dependent. Velocity decreases with falling frequency, delay increases. The relative deviation can be calculated according to equation 13.

As in the case of characteristic impedance, relative propagation velocity of RF cables is understood as the value it approaches for very high frequencies. If $D_c = D_i$ and $d_c = d_i$ it is dependent solely upon the dielectric constant ϵ_r and is defined as follows:

$$v_r = \frac{100}{\sqrt{\epsilon_r}} \quad \text{in \%} \quad (22)$$

Propagation velocity is measured at frequencies around 200 MHz as standard. Propagation velocity is also subject to variations. These variations have no direct influence upon transmission characteristics; they do, however, come to light, if cables have to be adjusted to equal electrical length, because after adjustment the cables of equal electrical length may show differences in geometrical length. If cables are to be used in applications where consistency of electrical length is important, we recommend that this is stated at the time of order placement, in order to allow us to select the cables from one manufacturing batch, whenever possible.

Electrical length and adjustment of length

The electrical length is defined as follows:

$$l_e = \frac{100 \cdot l}{v_r} \quad \text{in m} \quad (23)$$

l - geometrical length in m

v_r - relative propagation velocity in %

Between electrical length and phase angle the following relation applies:

$$\varphi = 2 \cdot \pi \cdot \frac{l_e}{300} \cdot f \quad \text{in rad} \quad (24)$$

l_e - electrical length in m

f - frequency in MHz

In many cases, cables with equal or defined differential electrical length are required. Typical examples are feeder cables for TV transmitters and cabling of antenna groups or antenna arrays. Such length adjustments can be made with precision. A typical value for the achievable accuracy is a phase angle tolerance of $\pm 5^\circ$ in the 470 to 860 MHz frequency band. In order to eliminate length variations through handling after adjustment, we recommend to have long lengths of cables length adjusted after installation; short cable lengths may, however, be supplied factory-adjusted.

The electrical length of RF cables is dependent upon temperature, and in case of air dielectric cables also upon the pressure and humidity of contained air. The influences are quite small, but must, however, be taken into account in case where the cables are very long as compared to the operating wavelength.

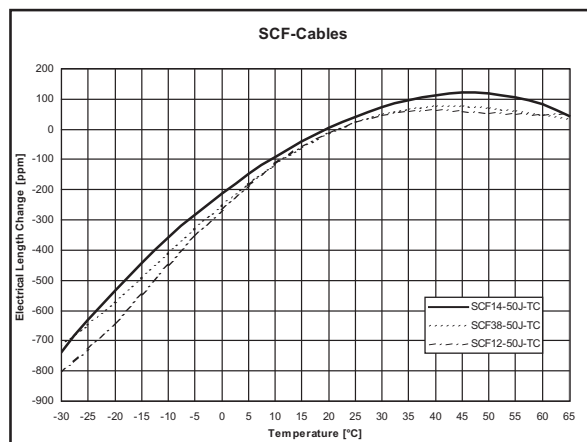

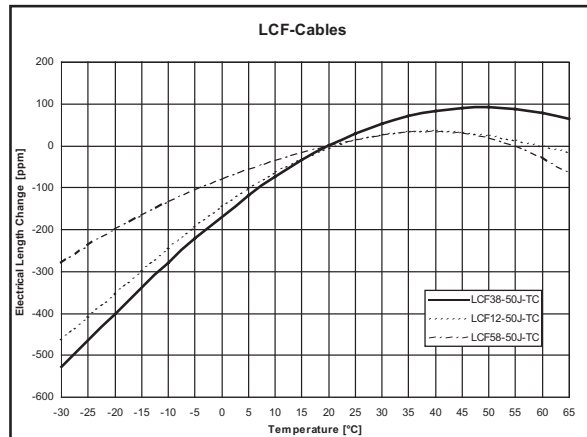

It is advisable to install length-adjusted cables so that they are all subject to the same ambient conditions such as temperature, solar radiation etc. Length-adjusted HELIFLEX® cables should be operated under a slight overpressure (the same for all cables) of approx. 0.2 bar of dry air or nitrogen.

For less critical applications, phase-stabilized cables can be supplied. These are cables that are aged in order to reduce hysteresis effects.

The variation of electrical length with temperature is also influenced by the kind of cable attachment to the support structure. Cables that can expand freely with temperature have different values than cables which are rigidly clamped down.

In the following diagrams typical figures of the electrical length change are shown for several cable types.

Coaxial Transmission Lines

The phase change for a given cable length and temperature range can be calculated with equation(25).

$$\Delta\varphi = 120 \cdot 10^{-6} \cdot \frac{l}{v_r} \cdot \Delta ppm \cdot f \quad \text{in Deg} \quad (25)$$

l - cable length in m

v_r - relative velocity of propagation in %

Δppm - electrical length change in ppm

f - frequency in MHz

Example:

A 10 m run of LCF12-50 is used in the temperature range from -10°C to 40°C (14° to 104°F) at 1 GHz.

In the above diagram the Δppm of approximately 280 can be read. The maximum phase change is

$$\Delta\varphi = 120 \cdot 10^{-6} \cdot \frac{10}{88} \cdot 280 \cdot 1000 = 3.8^\circ$$

Attenuation

The attenuation of RF cables is defined as follows:

$$\alpha = 10 \cdot \log(P_1 / P_2) \quad \text{in dB/100 m} \quad (26)$$

P_1 - input power into a 100 m long cable terminated with the nominal value of its characteristic impedance

P_2 - power at the far end of this cable

The construction of a cable influences the attenuation (in the case of copper conductors and at 20°C [68°F]) in accordance with the following equation:

$$\alpha_{20} = \frac{36,1}{Z_c} \left(\frac{k_i}{d_e} + \frac{k_a}{D_e} \right) \cdot \sqrt{f} + 9,1 \sqrt{\epsilon_r} \cdot tg\delta \cdot f$$

$$= \alpha_R + \alpha_G \quad \text{in dB/100 m} \quad (27)$$

Z_c - characteristic impedance in ohms

f - frequency in MHz

D_e - electrically equivalent outer conductor diameter in mm

d_e - electrically equivalent inner conductor diameter in mm

ϵ_r - relative permittivity of dielectric

$tg\delta$ - loss factor of dielectric

k_i - shape factor of inner conductor

k_a - shape factor of outer conductor

Coaxial Transmission Lines

The attenuation values are stated for 20 °C (68°F). The stated figures are typical. With rising ambient temperature the attenuation also rises, by 0.2% K. The attenuation also rises if the cable is heated up by the transmitted power. The maximum rise is as follows:

HELIFLEX® cable with PE dielectric $\alpha_t / \alpha_{20} = 1.14$

HELIFLEX® cable with PTFE dielectric $\alpha_t / \alpha_{20} = 1.20$

CELLFLEX® cable $\alpha_t / \alpha_{20} = 1.12$

α_t - attenuation of the cable at full mean power rating

Finally, attenuation rises in case of considerable mismatches at the cable end. The effect is illustrated in Fig. 1. The cable is assumed to be matched at the transmitter.

The attenuation of RF cables is mainly resistive attenuation α_R , which rises with the square root of frequency. For a given cable size, the resistive attenuation reaches a minimum for a dielectric constant of 1 (air dielectric). Resistive attenuation also decreases with increasing cable size.

Dielectric attenuation α_G rises proportionally with frequency. It is independent of cable size and determined only by quantity and quality of the dielectric material. Its share in total attenuation rises with frequency and cable size. Therefore, in particular the larger HELIFLEX® cable sizes have a very low material content dielectric. The same fact also prompted the introduction of loss foam CELLFLEX® cables (LCF).

Fig. 1 Attenuation increase due to mismatch at cable end (with cable matched at transmitter end)

Efficiency

The efficiency of a cable is the ratio between the power available to a load at the far end of the cable and the power put into it at the near end and is therefore an important parameter to compare several feeder cables.

$$\eta = \frac{P_2}{P_1} = 10^{-\left(\frac{\alpha_t \cdot \frac{l}{100} + A_r}{10}\right)} \quad (28)$$

P_2 - power at load

P_1 - input power

α_t - attenuation of cable (taking into account additional attenuation due to the power being used) in dB/100 m

A_r - additional attenuation through mismatch at cable end (see Fig.1)

l - cable length in m

Power rating

Power rating is the lower of the following two values: peak power rating and mean power rating.

Peak power rating

Peak power rating is the input power for which the peak RF voltage rating is reached, when the cable is operating in its matched condition. It is defined as:

$$\hat{P} = 500 \cdot \frac{\hat{U}^2}{Z_C} \quad \text{in kW} \quad (29)$$

\hat{U} - RF voltage rating (peak value) in kV

Z_C - characteristic impedance in Ω

Peak power rating is independent of frequency.

The stated values for peak RF voltage rating and peak power rating of HELIFLEX® cables are valid for dry air or dry nitrogen under normal atmospheric pressure.

RF voltage rating and peak power rating of HELIFLEX® cables are valid for dry air or dry nitrogen under normal atmospheric pressure.

As production testing of RF cables is done with DC voltage of twice the peak RF voltage rating, there is a safety factor of 2 in voltage and a safety factor of 4 in peak power rating.

Peak power rating of HELIFLEX® cables can be increased considerably by operating them under inner overpressure (suitable connectors for this operation are available for cable, sizes 3" and larger). Peak power rating decreases with altitude, if the cable inner is allowed to assume the pressure of the environment, see. Fig. 2.

Coaxial Transmission Lines

Although CELLFLEX® cables due to their dielectric type have a higher voltage strength than air dielectric cables, in practice the short sections of air line present at the cable ends when terminated with commonly used connector types limit the peak voltage ratings of CELLFLEX® cables to those of equivalent size air dielectric cables.

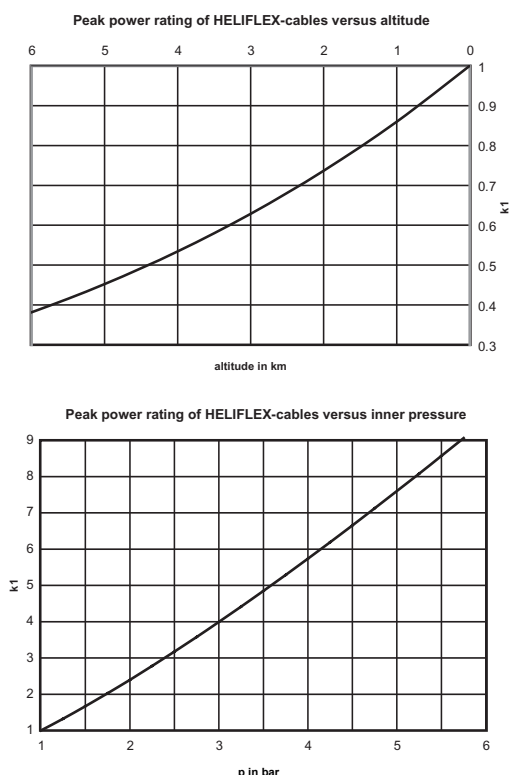

Fig. 2 Peak power rating of HELIFLEX® cables versus inner pressure and altitude

Mean power rating

Mean power rating is defined as:

$$\bar{P}_{\max} = \frac{0,8686 \cdot P_v}{2 \cdot \alpha_t} \quad \text{in kW} \quad (30)$$

P_v - maximum admissible power dissipation in W/m

α_t - attenuation under operation condition in dB/100 m

Mean power rating is the input power at which the inner conductor reaches a temperature agreed for a certain dielectric material. For most of the RFS cables these are:

HELIFLEX® (PTFE)	150°C (302°F)
HELIFLEX® (PE)	115°C (239°F)
CELLFLEX®	100°C (212°F)

Mean power rating decreases as frequency rises.

Mean power rating values are given for the following conditions:

- installed in still air of 40 °C (104°F)
- in case of HELIFLEX® cables, filled with air or nitrogen, under normal atmospheric pressure.

The variation of mean power rating with ambient temperature is given in Fig.3.

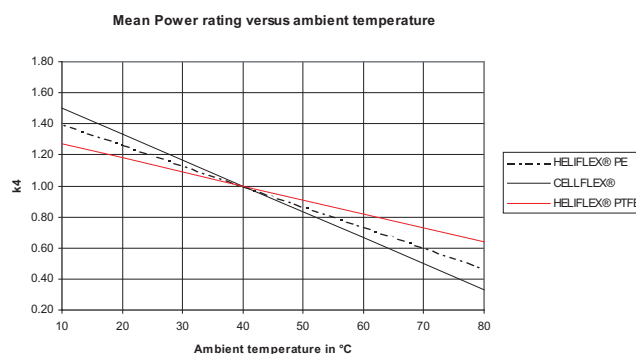

Fig. 3 mean power rating versus ambient temperature

Fig. 4 Mean power rating of HELIFLEX® cables versus inner pressure (air, nitrogen) for cables installed in air

If RF cables are subjected to direct solar radiation, mean power rating will decrease. The derating factor is given in Fig. 5.

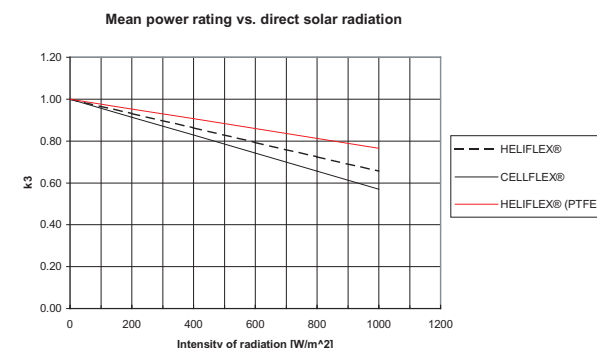

Fig. 5 Influence of direct solar radiation on mean power rating. Worst case: cable fully exposed and perpendicular to sun rays

Coaxial Transmission Lines

For mean power calculation of cables to be buried in the ground, the heat resistance of the cable jacket to air combination is replaced by the heat resistance of the soil, and the ambient temperature is replaced by the average soil temperature at the proposed cable laying depth.

As the heat resistivity of the soil is very dependent upon local conditions such as humidity and type of soil, and since the soil in the vicinity of RF cables which dissipate large heat power tends to dry out, it is necessary to have the correspondent information from the list given below.

Generally, it can be said for normal kinds of soil in moderate climates, that mean power rating of smaller cable sizes (if buried) increases whereas in the case of larger cable sizes it decreases.

If a buried, large cable is operating under inner overpressure, mean power rating doesn't increase as much as if this cable would be installed above ground.

When planning an RF cable system the following Data should be known:

Installation location details:

- height above sea level
- ambient temperature and intensity of solar radiation
- ground temperature, soil type and ground water level

Installation details:

- cable to be laid in masts, above-ground, in-ground or in ducts
- pressurization permissible
- heat dissipated by parallel cables
- connector types

Operating conditions:

- number and length of cables
- frequencies and permissible attenuation
- transmitter peak and average output power (\hat{P} and \bar{P})
- or the information to calculate these data, as given in Fig.6 antenna VSWR (s)

If the cable end is not terminated in its characteristic impedance, standing waves along the cable will result in higher power being dissipated at current and voltage maximums. Input power must, therefore, be reduced accordingly. In summary, therefore, the following conditions must be fulfilled when selecting a cable size for a certain power configuration.

$$\hat{P}_{\max} \geq \frac{\hat{P} \cdot s}{k_1} \quad (31)$$

$$\bar{P}_{\max} \geq \bar{P} \frac{s}{k_2 k_3 k_4} \quad (32)$$

\hat{P}, \bar{P} - peak power and mean power of transmitter

$\hat{P}_{\max}, \bar{P}_{\max}$ - peak power rating and mean power rating of cable

s - VSWR

k_1 - peak power rating factor for inner pressure (Fig.2)

k_2 - mean power rating factor for inner pressure (Fig.4)

k_3 - mean power rating factor for direct solar radiation (Fig.5)

k_4 - mean power rating factor for ambient temperature (Fig.3)

For cables operated above half their cut-off frequency in a non-matched condition, heat compensation between the extreme values of temperature along the cable can be expected. In this case, the VSWR in equation 32 may be replaced by the term

$$(s^2 + 1)/2 s.$$

If peak and average transmitter output power are known only in terms like carrier power, modulation depth etc., then these data can be computed as follows:

$$\hat{P} = P_R \cdot \hat{q} \quad (33)$$

$$\bar{P} = P_R \cdot \bar{q} \quad (34)$$

P_R - reference power of transmitter

\hat{q} - factor according to Fig.6

\bar{q} - factor according to Fig. 6

Coaxial Transmission Lines

Modulation	Reference Power PR	\hat{q}	\bar{q}
amplitude modulation	carrier power	$(1 + \hat{m})^2$	$1 + \frac{\bar{m}^2}{2}$
frequency modulation	transmitter power	1	1
pulse modulation	pulse power	1	$t_p \cdot f_p$
television (CCIR Standard)	peak sync. Power	1.73 ^[1]	0.71 ^[1]
		1.50 ^[2]	0.66 ^[2]
DAB OFDM	sum power	10 ^[3]	1
DVB OFDM	sum power	10 ^[3]	1

Fig. 6

- [1] audio to video power ratio 1:10
- [2] audio to video power ratio 1:20
- [3] Depending on the number of carriers, the theoretical value of \hat{q} can be very high. In practice, it is limited to about 10 by saturation effects of the transmitter output amplifier.

- \hat{m} - peak modulation depth
- \bar{m} - mean modulation depth
- t_p - pulse length in μs
- f_p - pulse repetition frequency in MHz

If several programs with peak power values P1, P2, etc., are transmitted simultaneously, then the resulting peak power is as follows:

$$\hat{P}_{res} = (\sqrt{\hat{P}_1} + \sqrt{\hat{P}_2} + \dots)^2 \quad (35)$$

Maximum operating frequency and cut-off frequency

Energy transmission in a coaxial RF cable takes place in the normal coaxial wave mode. Above cut-off frequency, which is a function of cables dimensions, other wave modes can also exist and the transmission properties are no longer defined. It is, therefore, generally not possible to operate RF cables above their cut-off frequency. An approximate value of cut-off frequency and the cut-off wavelength for RF cables can be computed as follows:

$$f_c = \frac{1,91 \cdot v_r}{D_i + d_a} \quad \text{in GHz} \quad (36)$$

$$\lambda_c = \pi \frac{D_i + d_a}{2} \cdot \frac{1}{10 \cdot v_r} \quad \text{in m} \quad (37)$$

- v_r - relative propagation velocity in %
- D_i - inner diameter of outer conductor in mm
- d_a - outer diameter of inner conductor in mm

In addition to cut-off frequencies, maximum operating frequencies of RF cables are stated. These give a certain safety margin from cut-off frequency. For some cables the maximum operating frequency is determined by other construction criteria and may then significantly deviate from cut-off frequency.

Measurements

If no alternative arrangements have been made, then measurements of the electrical properties of RF cables are made in accordance with IEC 61196-1: Radio-Frequency-Cables; Generic specification - General definitions, requirements and test methods.
